

Advanced Electro-Optical Modeling of III-Nitride Light Emitters

Project Manager
Akshay Shedbalkar

Principal Investigator
Prof. Dr. Bernd Witzigmann

Project Term
2015 - 2015

Project Areas
Optics, Quantum Optics and Physics
of Atoms, Molecules and Plasmas

Clusters
Linux Cluster Kassel

Institute
Center for Interdisciplinary
Nanostructure Science and
Technology

University
University Kassel

Introduction

As part of the research group POLARCON, we intend to study the active region carrier dynamics in III-nitride light emitting devices using quantummechanical non-equilibrium models, such as an empirical scattering theory or the non-equilibrium Green's function method (NEGF). This method is applied to the analysis of active regions for III-nitride light emitters with different crystals orientations for the first time. It will overcome the limits of present simulation methods, such as lack of tunneling currents and thermally activated currents from non-equilibrium carrier distributions in the prescence of radiative and non-radiative recombination. Using this model, we plan to improve the understanding of lasers and light emitting diodes (LEDs) for polar, semi-polar and non-polar configurations, in particular electro-optical efficiencies and threshold current densities.
