Computational Modelling of Multiple Photoswitches

Introduction

The computational modeling of molecular transformations in organic chemistry, e.g. photo-inducible isomerizations of azobenzenes allows one to predict and design novel photoswitches and their reaction pathways. Molecular switches are of high importance for biology and material science, and computational modelling of their properties is an important step prior to the synthesis and experimental investigation.

Methods

Molecular geometries and thermochemical, as well as spectral properties were computed using Density Functional Theory (DFT) and time dependent DFT such as the PBE0 or BHLYP functionals. Highly precise energies were obtained using ab-initio DLPNO-CCSD(T) with at least triple zeta basis sets.

Results

Several macrocycles containing multiple azobenzene units were synthesized and investigated. It was found that macrocyclic ring strain strongly influences the compounds thermal *Z*→*E* isomerization behavior, that could be used to for three-state photoswitching in a symmetric molecule. Furthermore, computations revealed that overcoming ring strain determines the rate determining step, making this unconventional switching behavior possible.

Project Manager
Prof. Dr. Hermann A. Wegner

Researchers
Andreas H. Heindl

Principal Investigator
Prof. Dr. Hermann A. Wegner

Project Term
2016 - 2019

Clusters
Skylla Cluster Gießen, FUCHS-CSC Frankfurt

Software
GAUSSIAN, ORCA

Institute
Institute of Organic Chemistry

University
Justus Liebig University Giessen

Funded by

Deutsche Forschungsgemeinschaft

Last Update: 2022-04-16 13:09
